- 1.2 Modeling approach 3

CAPÍTULO

DECISION MAKING UNDER UNCERTAINTY

PÁGINA 4

- 2.1 News Vendor Problem 4
 - Introduction — 4 • The Maximin Criterion — 4 • The Maximax Criterion — 4 • The Minimax Regret Criterion — 5

Chapter 1

Introduction

What is Operations Research? A way to use existing resources more efficiently. Efficiency is the key of this lectures. We are going to talk about mathematical, technical and everyday models, but what is a model? A model is a selective representation of reality. We are going to talk from models ranging from simulation ones (aerodynamics) to economical models or industrial ones.

The reasons why we use models may seem obvious, some of them may be time efficiency, safety... In the end the objective is to predict outcomes and optimize how we act.

1.1 Types of models

According to the type of data we have, we talk about two types of models

- **Deterministic:** All relevant data is assumed to be known with certainty.
- **Stochastic:** Some of the data are uncertain

Models could be considered as deterministic and stochastic according to the variables that you are considering.

1.2 Modeling approach

1. Formulate the problem
2. Construct a mathematical model
3. Derive a solution from the model
4. Establish control over the solution
5. Implement the solution

Chapter 2

Decision Making Under Uncertainty

2.1 News Vendor Problem

How much production should you allocate in advance before knowing how much demand there's going to be? We should make a model.

2.1.1 Introduction

Nature is not against you, the outcome is indifferent. The problem structure will be:

1. Decision: You select an action a_i from the set of possible actions $A = \{a_1, a_2, \dots, a_k\}$.
2. A state of nature s_j occurs from a set of possible states $S = \{s_1, s_2, \dots, s_n\}$.
3. p_j = probability that state s_j is observed.
4. You receive a reward r_{ij} based on a_i and s_j .

Well our next step should be to build a Reward Table for the problem, in which in return you receive for each possible combination of decision and states of nature.

Decision	State of Nature				Minimum Return	Maximum Return
	0	1	2	3		
0	0	0	0	0	0	0
1	-10	15	15	15	-10	15
2	-20	5	30	30	-20	30
3	-30	-5	20	45	-30	45

Table 2.1: Reward Table

2.1.2 The Maximin Criterion

This criterion chooses the action that minimizes the worst outcome. We see that the minimum risk option is buying no newspapers, as the minimum return for all the others is negative (if you can't sell a single newspaper). This is extremely risk averse.

2.1.3 The Maximax Criterion

On the other hand, this criterion maximizes the best outcome. In this case we see that the maximum outcome would come from buying three newspapers (and selling all of them). This is extremely optimistic.

2.1.4 The Minimax Regret Criterion

This criterion minimizes the maximum regret, being regret the extra amount you could have obtained if you had known the state of nature beforehand. In this case we see that the minimum regret would be obtained if you

Decision	State of Nature				Maximum Regret
	0	1	2	3	
0	0	15	30	45	45
1	10	0	15	30	30
2	20	10	0	15	20
3	30	20	10	0	30

Table 2.2: Regret Table

bought 2 newspapers. This criterion is way more reasonable and approaches a more sensitive solution.
