# Outline

## 1. Introduction

## 2. Methods

### 2.1 Direct Imaging

### 2.2 Radial Velocity

### 2.3 Transit Method

## 3. Habitability

## 4. References

# What is an Exoplanet?

An exoplanet is a planet that orbits around a star-like object that has the conditions necessary for *life*.

- Rocky composition
- Mild temperatures
- Biomarker elements

# First steps

Target ID: 309661100, Cadence: 442882

Figure: Single-frame Star luminosity

# Detection Methods<sup>1</sup>

## ***Direct Imaging***

Photo like pixel analysis.

## ***Radial Velocity***

Gravitational wobble on stars, Doppler effect.

## ***Transit Method***

Time and size of planet occlusion.

## ***Gravitational Microlensing***

Lensing by space-time warping with secondary stars

---

<sup>1</sup>There are also other methods related with machine learning that go over the scope of this presentation, although their work is centered around classification. [Terry, 2023]

# Direct Imaging

## Coronagraph

Small object used to occlude light source's beams.

- Requires proximity
- Requires decent size

Space-shade project. [NASA University of Colorado, 2017]

# Radial Velocity

Astrometry [ESA, 2019]

# Transit Method

[Hans J. Deeg, 2024]

- Easiest to analyze
- Very cost effective
- Demo

Figure: Exoplanet transit occlusion

# Habitability

- Only in our galaxy there is an estimation of **10 billion** exoplanets.
- Earth-like size does not guarantee atmosphere.
- Elements associated with life are very hard to detect.
- Magnetic field presence is unknown.
- Planets may **outnumber** stars in the sky.
